

Spectral radius and Hamiltonicity of graphs with large minimum degree

V. Nikiforov*

Dedicated to the memory of Miroslav Fiedler

Abstract

This paper presents sufficient conditions for Hamiltonian paths and cycles in graphs. Letting $\lambda(G)$ denote the spectral radius of the adjacency matrix of a graph G , the main results of the paper are:

(1) Let $k \geq 1$, $n \geq k^3/2 + k + 4$, and let G be a graph of order n , with minimum degree $\delta(G) \geq k$. If

$$\lambda(G) \geq n - k - 1,$$

then G has a Hamiltonian cycle, unless $G = K_1 \vee (K_{n-k-1} + K_k)$ or $G = K_k \vee (K_{n-2k} + \overline{K}_k)$.

(2) Let $k \geq 1$, $n \geq k^3/2 + k^2/2 + k + 5$, and let G be a graph of order n , with minimum degree $\delta(G) \geq k$. If

$$\lambda(G) \geq n - k - 2,$$

then G has a Hamiltonian path, unless $G = K_k \vee (K_{n-2k-1} + \overline{K}_{k+1})$ or $G = K_{n-k-1} + K_{k+1}$.

In addition, it is shown that in the above statements, the bounds on n are tight within an additive term not exceeding 2.

Keywords: *Hamiltonian cycle; Hamiltonian path; minimum degree; spectral radius.*

AMS classification: 05C50, 05C35.

1 Introduction

In this paper we present sufficient spectral conditions for Hamiltonian paths and cycles in graphs with large minimum degree.

Write $\lambda(G)$ for the spectral radius of the adjacency matrix of a graph G . In 2010, Fiedler and Nikiforov [9] gave some bounds on $\lambda(G)$ implying the existence of Hamiltonian paths and

*Department of Mathematical Sciences, University of Memphis, Memphis TN 38152, USA

cycles in G . This work motivated further research, as could be seen, e.g., in [1, 10, 13, 14, 15, 16, 17, 21].

The aim of this paper is to extend some recent results by Benediktovich [1], Li and Ning [14], and Ning and Ge [17]. To state those results we need to introduce three families of extremal graphs, which are denoted by $L_k(n)$, $M_k(n)$ and $N_k(n)$.

Write K_s and \overline{K}_s for the complete and the edgeless graphs of order s . Given graphs G and H , write $G \vee H$ for their join and $G + H$ for their disjoint union.

The graphs $L_k(n)$. For any $k \geq 1$ and $n \geq 2k + 1$, let

$$L_k(n) := K_1 \vee (K_{n-k-1} + K_k).$$

Thus, the graph $L_k(n)$ consists of a K_{n-k} and a K_{k+1} sharing a single vertex.

The graphs $M_k(n)$. For any $k \geq 1$ and $n \geq 2k + 1$, let

$$M_k(n) := K_k \vee (K_{n-2k} + \overline{K}_k).$$

Thus, the graph $M_k(n)$ consists of a K_{n-k} and a set of k independent vertices all joined to some k vertices of the K_{n-k} .

The graphs $N_k(n)$. For any $k \geq 1$ and $n \geq 2k + 1$, let

$$N_k(n) := K_k \vee (K_{n-2k-1} + \overline{K}_{k+1}).$$

Thus, the graph $N_k(n)$ consists of a K_{n-k-1} and a set of $k + 1$ independent vertices all joined to some k vertices of the K_{n-k-1} .

Note that for any admissible k and n , the graphs $L_k(n)$ and $M_k(n)$ contain no Hamiltonian cycle and $N_k(n)$ contains no Hamiltonian path, whereas the minimum degree of each of them is exactly k .

The graphs $M_k(n)$ and $N_k(n)$ were used by Erdős [7] as extremal graphs in his results on Hamiltonicity of graphs with large minimum degree. Moreover, recently Li and Ning [14] showed that $M_k(n)$ and $N_k(n)$ are relevant also for some spectral analogs of Erdős's results:

Theorem 1 (Li, Ning [14]) *Let $k \geq 0$ and G be a graph of order n , with minimum degree $\delta(G) \geq k$.*

(1) If $n \geq \max \{6k + 10, (k^2 + 7k + 8)/2\}$ and

$$\lambda(G) \geq \lambda(N_k(n)),$$

then G has a Hamiltonian path, unless $G = N_k(n)$;

(2) If $k \geq 1$, $n \geq \max \{6k + 5, (k^2 + 6k + 4)/2\}$, and

$$\lambda(G) \geq \lambda(M_k(n)),$$

then G has a Hamiltonian cycle, unless $G = M_k(n)$.

Theorem 1 seems as good as one can get, yet somewhat subtler and stronger statements have been proved for $k = 1, 2$.

Theorem 2 (Ning, Ge [17]) *Let $n \geq 7$ and G be a graph of order n , with minimum degree $\delta(G) \geq 1$. If*

$$\lambda(G) > n - 3,$$

then G has a Hamiltonian path, unless $G = N_1(n)$.

Theorem 3 (Benediktovich [1]) *Let $n \geq 10$ and let G be a graph of order n , with minimum degree $\delta(G) \geq 2$. If*

$$\lambda(G) \geq n - 3,$$

then G has a Hamiltonian cycle, unless $G = L_2(n)$ or $G = M_2(n)$.

Note that in our renditions of Theorems 2 and 3, a few details have been suppressed from the original theorems in order to highlight them as instances of more general statements, in which $\delta(G)$ is bounded by a parameter.

Thus, here we propose the following two theorems, which generalize Theorems 2 and 3, and strengthen Theorem 1 for n sufficiently large:

Theorem 4 *Let $k \geq 1$, $n \geq k^3/2 + k + 4$, and let G be a graph of order n , with minimum degree $\delta(G) \geq k$. If*

$$\lambda(G) \geq n - k - 1,$$

then G has a Hamiltonian cycle, unless $G = L_k(n)$ or $G = M_k(n)$.

Theorem 5 *Let $k \geq 1$, $n \geq k^3/2 + k^2/2 + k + 5$, and let G be a graph of order n , with minimum degree $\delta(G) \geq k$. If*

$$\lambda(G) \geq n - k - 2,$$

then G has a Hamiltonian path, unless $G = N_k(n)$ or $G = K_{n-k-1} + K_{k+1}$.

We shall give independent, self-contained proofs of Theorems 4 and 5, although many smart ideas could be readily borrowed from each of the papers [1], [14], and [17]. Crucial points of our arguments are based on the following straightforward theorems, whose proofs are nevertheless long and technical:

Theorem 6 *Let $k \geq 1$, $n \geq k^3/2 + k + 4$, and let G be a graph of order n , with minimum degree $\delta(G) \geq k$.*

- (i) If G is a subgraph of $M_k(n)$, then $\lambda(G) < n - k - 1$, unless $G = M_k(n)$.*
- (ii) If G is a subgraph of $L_k(n)$, then $\lambda(G) < n - k - 1$, unless $G = L_k(n)$.*

Theorem 7 Let $k \geq 1$, $n \geq k^3/2 + k^2/2 + k + 5$, and let G be a graph of order n , with minimum degree $\delta(G) \geq k$.

(i) If G is a subgraph of $N_k(n)$, then $\lambda(G) < n - k - 2$, unless $G = N_k(n)$.

(ii) If G is a subgraph of $K_{n-k-1} + K_{k+1}$, then $\lambda(G) < n - k - 2$, unless $G = K_{n-k-1} + K_{k+1}$.

One can ask how tight are the lower bounds on n in the premises of Theorems 4–7. This question has been brought up by Ge and Ning in [10], after they reduced by half the bound on n in a previous version of Theorem 6. In fact, the bounds turn out to be tight within an additive term not exceeding 2:

Proposition 8 If $k \geq 2$ and $2k + 1 \leq n \leq k^3/2 + k + 1$, there exists a graph G of order n , with minimum degree $\delta(G) \geq k$ such that G is a proper subgraph of $M_k(n)$, and $\lambda(G) > n - k - 1$.

Proposition 9 If $k \geq 2$ and $2k + 1 \leq n \leq k^3/2 + k^2/2 + k + 2$, there exists a graph G of order n , with minimum degree $\delta(G) \geq k$ such that G is a proper subgraph of $N_k(n)$, and $\lambda(G) > n - k - 1$.

Clearly, Propositions 8 and 9 leave room for some ultimate nitpicking, which we skip.

The rest of the paper is structured as follows: In Section 2, we introduce some notation, recall some details about graph closure, and state a few results that will be used in the proofs of Theorems 4–7 and Propositions 8 and 9. The proofs themselves are given in Section 3. The last Section 4 is dedicated to a brief discussion and some open problems.

2 Notation and preliminaries

For graph notation and terminology undefined here we refer the reader to [2]. We write $A(G)$ for the adjacency matrix of a graph G , and denote the quadratic form of $A(G)$ by $\langle A(G) \mathbf{x}, \mathbf{x} \rangle$, where \mathbf{x} is a vector of size equal to the order of G . Note that if G is of order n and $\mathbf{x} := (x_1, \dots, x_n)$, then

$$\langle A(G) \mathbf{x}, \mathbf{x} \rangle = 2 \sum_{\{i,j\} \in E(G)} x_i x_j.$$

If G is a graph of order n , we write d_1, \dots, d_n for the degrees of G indexed in ascending order.

A graph G is called *Hamiltonian-connected* if for any two vertices u and v of G , there is a Hamiltonian path in G whose ends are u and v .

We shall need the concept of graph closure, used implicitly by Ore in [19, 20], and developed further by Bondy and Chvátal in [3]: Fix an integer $k \geq 0$. Given a graph G , perform the following operation: if there are two nonadjacent vertices u and v with $d_G(u) + d_G(v) \geq k$, add the edge uv to $E(G)$. A k -closure of G is a graph obtained from G by successively applying this operation as long as possible. As it turns out, the k -closure of G is unique, that is to say, it does not depend on the order in which edges are added; see [3] for details.

Write $\text{cl}_k(G)$ for the k -closure of G and note its main property:

If u and v are nonadjacent vertices of $\text{cl}_k(G)$, then $d_{\text{cl}_k(G)}(u) + d_{\text{cl}_k(G)}(v) \leq k - 1$.

The usefulness of graph closure is demonstrated by the following facts, due essentially to Ore [19, 20]:

- A graph G of order n has a Hamiltonian path if and only if $\text{cl}_{n-1}(G)$ has one.
- A graph G of order n has a Hamiltonian cycle if and only if $\text{cl}_n(G)$ has one.
- A 2-connected graph G of order n is Hamiltonian-connected if and only if $\text{cl}_{n+1}(G)$ is Hamiltonian-connected.

For convenience we restate the last two statements in more usable form.

Theorem 10 (Ore [20]) *If G is a graph of order n and $d_u + d_v \geq n$ for any two distinct nonadjacent vertices u and v , then G has a Hamiltonian cycle.*

Theorem 11 (Ore [20]) *If G is a 2-connected graph of order n and $d_u + d_v \geq n + 1$ for any two distinct nonadjacent vertices u and v , then G is Hamiltonian-connected.*

We shall also need two classical results of Chvátal [5] on Hamiltonicity of graphs.

Theorem 12 (Chvátal [5]) *Let G be a graph of order n , with degrees d_1, \dots, d_n . If G has no Hamiltonian cycle, then there is an integer $s < n/2$ such that $d_s \leq s$ and $d_{n-s} \leq n - s - 1$.*

Corollary 13 (Chvátal [5]) *Let G be a graph of order n , with degrees d_1, \dots, d_n . If G has no Hamiltonian path, then there is an integer $s < (n + 1)/2$ such that $d_s \leq s - 1$ and $d_{n-s+1} \leq n - s - 1$.*

Finally, we shall need the following inequality, proved in [18]:

Theorem 14 ([11], [18]) *If G is a graph of order n , with m edges, and minimum degree δ , then*

$$\lambda(G) \leq \frac{\delta - 1}{2} + \sqrt{2m - n\delta + \frac{(\delta + 1)^2}{4}}. \quad (1)$$

For connected graphs inequality (1) has been proved independently by Hong, Shu and Fang in [11].

The following observation is often useful in applications of inequality (1).

Proposition 15 ([11], [18]) *If $2m \leq n(n - 1)$, the function*

$$f(x) = \frac{x - 1}{2} + \sqrt{2m - nx + \frac{(x + 1)^2}{4}}$$

is decreasing in x for $x \leq n - 1$.

3 Proofs

3.1 Proof of Theorem 6

Proof Set for short $\lambda := \lambda(G)$, and let $\mathbf{x} = (x_1, \dots, x_n)$ be a positive unit eigenvector vector to λ . Recall that Rayleigh's principle implies that

$$\lambda = \langle A(G) \mathbf{x}, \mathbf{x} \rangle.$$

The idea of the proofs below exploits the fact that both $M_k(n)$ and $L_k(n)$ consist of a K_{n-k} , together with an “outgrowth” of bounded order. It turns out that if n is large, the total contribution to $\langle A(G) \mathbf{x}, \mathbf{x} \rangle$ of all edges incident to the “outgrowth” is less than the contribution of a single edge of the K_{n-k} .

Now we give the details.

Proof of (i)

Assume that G is a proper subgraph of $M_k(n)$. Clearly, we may assume that G is obtained by omitting just one edge $\{u, v\}$ of $M_k(n)$.

Write X for the set of vertices of $M_k(n)$ of degree k , let Y be the set of their neighbors, and let Z be the set of the remaining $n - 2k$ vertices of $M_k(n)$.

Since $\delta(G) \geq k$, we see that G must contain all the edges between X and Y . Therefore, $\{u, v\} \subset Y \cup Z$, with three possible cases: (a) $\{u, v\} \subset Y$; (b) $u \in Y, v \in Z$; (c) $\{u, v\} \subset Z$. We shall show that case (c) yields a graph of no smaller spectral radius than case (b), and that case (b) yields a graph of no smaller spectral radius than case (a).

Indeed, by symmetry, we have $x_i = x_j$ for any $i, j \in X$; likewise, $x_i = x_j$ for any $i, j \in Y \setminus \{u, v\}$ and for any $i, j \in Z \setminus \{u, v\}$. Thus, let

$$\begin{aligned} x &:= x_i, \quad i \in X, \\ y &:= x_i, \quad i \in Y \setminus \{u, v\}, \\ z &:= x_i, \quad i \in Z \setminus \{u, v\}. \end{aligned}$$

Suppose that case (a) holds, that is, $\{u, v\} \subset Y$. Choose a vertex $w \in Z$, remove the edge $\{v, w\}$ and add the edge $\{u, v\}$. If $x_w > x_v$, swap the entries x_v and x_w ; write \mathbf{x}' for the resulting vector.

First, note that \mathbf{x}' is a unit vector and that the obtained graph G' is covered by case (b). We see that

$$\langle A(G') \mathbf{x}', \mathbf{x}' \rangle - \langle A(G) \mathbf{x}, \mathbf{x} \rangle = (x'_v - x_v) \sum_{i \in X} x_i \geq 0,$$

and, by the Rayleigh principle, $\lambda(G') \geq \lambda(G)$, as claimed.

Essentially the same argument proves that case (c) yields a graph of no smaller spectral radius than case (b). Therefore, we may assume that $\{u, v\} \subset Z$. Hence, the vertices u and v

are symmetric, and so $x_u = x_v$. Set $t := x_u$ and note that the n eigenequations of G are reduced to four equations involving just the unknowns x, y, z , and t :

$$\lambda x = ky, \quad (2)$$

$$\lambda y = kx + (k-1)y + (n-2k-2)z + 2t, \quad (3)$$

$$\lambda z = ky + (n-2k-3)z + 2t, \quad (4)$$

$$\lambda t = ky + (n-2k-2)z. \quad (5)$$

We find that

$$x = \frac{k}{\lambda}y, \quad (6)$$

$$z = \left(1 - \frac{k^2}{\lambda(\lambda+1)}\right)y, \quad (7)$$

$$t = \frac{\lambda+1}{\lambda+2} \left(1 - \frac{k^2}{\lambda(\lambda+1)}\right)y.$$

Further, note that if we remove all edges between X and Y and add the edge $\{u, v\}$ to G , we obtain the graph $K_{n-k} + \bar{K}_k$. Letting \mathbf{x}'' be the restriction of \mathbf{x} to K_{n-k} , we find that

$$\langle A(K_{n-k}) \mathbf{x}'', \mathbf{x}'' \rangle = \langle A(G) \mathbf{x}, \mathbf{x} \rangle + 2t^2 - 2k^2xy = \lambda + 2t^2 - 2k^2xy.$$

But since $\|\mathbf{x}''\|^2 = 1 - kx^2$, we see that¹

$$\lambda + 2t^2 - 2k^2xy = \langle A(K_{n-k}) \mathbf{x}'', \mathbf{x}'' \rangle \leq \lambda(K_{n-k}) \|\mathbf{x}''\|^2 = (n-k-1)(1-kx^2).$$

Assume for a contradiction that $\lambda \geq n-k-1$. This assumption, together with above inequality, yields

$$\lambda + 2t^2 - 2k^2xy \leq (1-kx^2)\lambda,$$

and therefore

$$2t^2 - 2k^2xy \leq -kx^2\lambda.$$

Now, (6) and (7) imply that

$$\frac{k^3}{2\lambda}y^2 \geq 2t^2 = \left(\frac{\lambda+1}{\lambda+2}\right)^2 \left(1 - \frac{k^2}{\lambda(\lambda+1)}\right)^2 y^2.$$

Cancelling y^2 and applying Bernoulli's inequality to the right side, we get

$$\begin{aligned} k^3 &\geq 2\lambda \left(1 - \frac{1}{\lambda+2}\right)^2 \left(1 - \frac{k^2}{\lambda(\lambda+1)}\right)^2 > 2\lambda - \frac{4\lambda}{\lambda+2} - \frac{4k^2}{\lambda+1} \\ &> 2\lambda - \frac{4\lambda + 4k^2}{\lambda+1}. \end{aligned}$$

¹This equation was suggested by Ge and Ning in [10] instead of the inequality $\|\mathbf{x}''\| < 1$ used in a previous version of the present proof.

Using the inequalities $\lambda \geq n - k - 1 \geq k^3/2 + 3$, we easily find that

$$\frac{4\lambda + 4k^2}{\lambda + 1} \leq 6,$$

and so,

$$k^3 > 2\lambda - \frac{4\lambda + 4k^2}{\lambda + 1} > k^3 + 6 - 6 = k^3,$$

a contradiction, completing the proof of (i).

Proof of (ii)

As in (i), assume that G is a subgraph of $L_k(n)$ obtained by omitting just one edge $\{u, v\}$ of $L_k(n)$. Recall that $L_k(n)$ consists of a K_{n-k} and a K_{k+1} sharing a single vertex, say w . Let Y be the set $\{w\}$, write X for the set of vertices of K_{k+1} that are distinct from w , and write Z for the set of vertices of K_{n-k} that are distinct from w .

Clearly, the condition $\delta(G) \geq k$ implies that $\{u, v\} \subset Y \cup Z$; among the three possible placements of $\{u, v\}$, the case $\{u, v\} \subset Z$ yields a graph with maximum spectral radius, so we assume that $\{u, v\} \subset Y$. Now, by symmetry, we see that $x_i = x_j$ for any $i, j \in X$; likewise, $x_u = x_v$ and $x_i = x_j$ for any $i, j \in Z \setminus \{u, v\}$. Thus, let

$$\begin{aligned} x &:= x_i, \quad i \in X, \\ y &:= x_w, \quad i \in Y, \\ z &:= x_i, \quad i \in Z \setminus \{u, v\}, \\ t &:= x_u = x_v. \end{aligned}$$

The n eigenequations of G now reduce to the four equations

$$\begin{aligned} \lambda x &= y + (k - 1)x, \\ \lambda y &= kx + (n - 2k - 3)z + 2t, \\ \lambda z &= y + (n - 2k - 4)z + 2t, \\ \lambda t &= y + (n - 2k - 3)z. \end{aligned}$$

Hence, we find that

$$\begin{aligned} x &= \frac{1}{\lambda - k + 1}y, \\ z &= \left(1 - \frac{k}{(\lambda - k + 1)(\lambda + 1)}\right)y, \\ t &= \frac{\lambda + 1}{\lambda + 2} \left(1 - \frac{k}{(\lambda - k + 1)(\lambda + 1)}\right)y. \end{aligned}$$

Further, if we delete all edges incident to vertices in X and add the edge $\{u, v\}$, we obtain the graph $K_{n-k} + \overline{K}_k$.

Assume for a contradiction that $\lambda \geq n - k - 1$. Reasoning as in the proof of (i), we get the inequality

$$\frac{k(k-1)}{2(\lambda-k+1)^2}y^2 + \frac{k}{\lambda-k+1}y^2 > t^2 = \left(\frac{\lambda+1}{\lambda+2}\right)^2 \left(1 - \frac{k}{(\lambda-k+1)(\lambda+1)}\right)^2 y^2,$$

which in turn yields

$$\frac{k(k-1)}{2(\lambda-k+1)} + k > \lambda - k + 1 - \frac{2(\lambda-k+1)}{\lambda+2} - \frac{2k}{\lambda+1} > \lambda - k - 1 \cdot (1 - kx^2)$$

Hence, using the inequality $\lambda \geq n - k - 1 \geq k^3/2 + 3$, we find that

$$\begin{aligned} k(k-1) &> 2(\lambda-k+1)(\lambda-2k-1) \\ &> (k^3 - 2k + 8) \left(\frac{k^3}{2} - 2k + 2\right) \\ &> 2k^3 - 4k + 16. \end{aligned}$$

It is not hard to see that this inequality is a contradiction for $k \geq 2$, completing the proof of Theorem 6. \square

3.2 Proof of Theorem 7

Proof The proof of (ii) is obvious. On the other hand, the proof of (i) is very similar to the proof of clause (i) of Theorem 6, so we skip its beginning, and state the starting system of equations, obtained with the same choice of variables as in equations (2)-(5):

$$\begin{aligned} \lambda x &= ky, \\ \lambda y &= (k+1)x + (k-1)y + (n-2k-3)z + 2t, \\ \lambda z &= ky + (n-2k-4)z + 2t, \\ \lambda t &= ky + (n-2k-3)z. \end{aligned}$$

Solving this system with respect to y , we find that

$$x = \frac{k}{\lambda}y, \tag{8}$$

$$z = \left(1 - \frac{k(k+1)}{\lambda(\lambda+1)}\right)y, \tag{9}$$

$$t = \frac{\lambda+1}{\lambda+2} \left(1 - \frac{k(k+1)}{\lambda(\lambda+1)}\right)y. \tag{10}$$

Assume for a contradiction that $\lambda \geq n - k - 2$. Proceeding further as in the proof of clause (i) of Theorem 6, we get the inequalities

$$\begin{aligned}\langle A(K_{n-k-1}) \mathbf{x}'', \mathbf{x}'' \rangle &= \langle A(G) \mathbf{x}, \mathbf{x} \rangle + 2t^2 - 2k(k+1)xy = \lambda + 2t^2 - 2k(k+1)xy \\ \langle A(K_{n-k-1}) \mathbf{x}'', \mathbf{x}'' \rangle &\leq (n-k-2) \left(1 - (k+1)x^2\right) \leq \lambda \left(1 - (k+1)x^2\right).\end{aligned}$$

Hence,

$$2k(k+1)xy - (k+1)\lambda x^2 \geq 2t^2.$$

Using (8), (9) and (10), after simple algebra we get

$$k^2(k+1) > 2\lambda \left(1 - \frac{1}{\lambda+2}\right)^2 \left(1 - \frac{k(k+1)}{\lambda(\lambda+1)}\right)^2.$$

Applying the Bernoulli inequality to the right-side of the above inequality, we find that

$$k^2(k+1) > 2\lambda - \frac{4\lambda}{\lambda+2} - \frac{4k(k+1)}{\lambda+1} \geq 2\lambda - \frac{4\lambda + 4k(k+1)}{\lambda+1}$$

Now in view of $\lambda \geq n - k - 2 \geq k^3/2 + k^2/2 + 3$, we easily see that

$$\frac{4\lambda + 4k(k+1)}{\lambda+1} \leq 6,$$

and so,

$$k^2(k+1) > 2\lambda - 6 \geq k^3 + k^2,$$

a contradiction, completing the proof of Theorem 7. \square

3.3 Proof of Theorem 4

Proof Let $k \geq 1$, $n \geq k^3/4 + k + 4$, and let G be a graph of order n , with $\delta(G) \geq k$. Write m for the number of edges of G , and set $\delta := \delta(G)$.

Assume that $\lambda(G) \geq n - k - 1$, but G has no Hamiltonian cycle. To prove the theorem we need to show that $G = L_k(n)$ or $G = M_k(n)$. Note that, in view of Theorem 6, it is sufficient to prove that $\text{cl}_n(G) = L_k(n)$ or $\text{cl}_n(G) = M_k(n)$, so this will be our main goal.

Clearly, $\text{cl}_n(G)$ has no Hamiltonian cycle and

$$\delta(\text{cl}_n(G)) \geq \delta(G) \geq k, \quad \lambda(\text{cl}_n(G)) \geq \lambda(G) \geq n - k - 1,$$

so for the rest of the proof we assume that $G = \text{cl}_n(G)$. The main consequence of this assumption is that

$$d_i + d_j \leq n - 1 \tag{11}$$

for every two nonadjacent vertices i and j .

Next, since G has no Hamiltonian cycle, Theorem 12 implies that there is an integer $s < n/2$ such that $d_s \leq s$ and $d_{n-s} \leq n-s-1$. Obviously, $s \geq \delta \geq k$, and we easily find an upper bound on $2m$:

$$\begin{aligned} 2m &= \sum_{i=1}^s d_i + \sum_{i=s+1}^{n-s} d_i + \sum_{i=n-s+1}^n d_i \\ &\leq s^2 + (n-2s)(n-s-1) + s(n-1) \\ &= n^2 - 2sn + 3s^2 + s - n. \end{aligned}$$

Clearly, the expression $n^2 - 2sn + 3s^2 + s - n$ is convex in s ; hence it is maximal in s for $s = \delta$ or $s = (n-1)/2$. Hence, either

$$2m \leq n^2 - 2\delta n + 3\delta^2 + \delta - n \quad (12)$$

or

$$2m \leq n^2 - (n-1)n + 3\frac{(n-1)^2}{4} + \frac{(n-1)}{2} - n. \quad (13)$$

On the other hand, inequality (1) implies that

$$n - k - 1 \leq \lambda(G) \leq \frac{\delta - 1}{2} + \sqrt{2m - n\delta + \frac{(\delta + 1)^2}{4}}.$$

Hence, in view of Proposition 15, we get

$$n - k - 1 \leq \lambda(G) \leq \frac{k - 1}{2} + \sqrt{2m - nk + \frac{(k + 1)^2}{4}},$$

which, after some algebra, gives

$$2m \geq n^2 - 2kn + 2k^2 + k - n. \quad (14)$$

Next, we prove that $s = k$. Indeed, if $s \geq k + 1$, then (12) and (13) imply that either

$$n^2 - 2(k+1)n + 3(k+1)^2 + k + 1 - n \geq n^2 - 2kn + 2k^2 + k - n$$

or

$$n^2 - (n-1)n + \frac{3}{4}(n-1)^2 + \frac{1}{2}(n-1) - n \geq n^2 - 2kn + 2k^2 + k - n.$$

Each of these inequalities leads to a contradiction, so we have $s = k$, and thus $\delta = k$. Therefore,

$$d_1 = \dots = d_k = k.$$

Our next goal is to show that $d_{k+1} \geq n - k - 1 - k^2$. Indeed, suppose that

$$d_{k+1} < n - k - 1 - k^2.$$

Now, using Theorem 12, we get

$$\begin{aligned}
2m &= \sum_{i=1}^k d_i + d_{k+1} + \sum_{i=k+2}^{n-k} d_i + \sum_{i=n-k+1}^n d_i \\
&< k^2 + n - k - 1 - k^2 + (n - 2k - 1)(n - k - 1) + k(n - 1) \\
&= n^2 - 2kn + 2k^2 + k - n,
\end{aligned}$$

contradicting (14). Hence $d_i \geq n - k - 1 - k^2$ for every $i \in \{k + 1, \dots, n\}$.

Next, we shall show that the vertices $k + 1, \dots, n$ induce a complete graph in G . Indeed, let $i \in \{k + 1, \dots, n\}$ and $j \in \{k + 1, \dots, n\}$ be two distinct vertices of G . If they are nonadjacent, then

$$\begin{aligned}
d_i + d_j &\geq 2n - 2k - 2 - 2k^2 \\
&\geq n + k^3 + k + 4 - 2k - 2 - 2k^2 \\
&= n - 1 + k^3 - 2k^2 - k + 3 > n - 1,
\end{aligned}$$

contradicting (11).

Write X for the vertex set $\{1, \dots, k\}$. Write Y for the set of vertices in $\{k + 1, \dots, n\}$ having neighbors in X . It is easy to see that $Y \neq \emptyset$, since $|X| = k$ and so any vertex in X must have a neighbor in $\{k + 1, \dots, n\}$.

In fact, every vertex from Y is adjacent to every vertex in X . Indeed, suppose that this is not the case, and let $w \in \{k + 1, \dots, n\}$, $u \in X$, $v \in X$ be such that w is adjacent to u , but not to v . We see that

$$d_w + d_v \geq n - k + k = n,$$

contradicting (11).

Next, let $l := |Y|$ and note that $1 \leq l \leq k$, since $d_1 = k$. If $l = 1$, then $G = L_k(n)$, and if $l = k$, then $G = M_k(n)$. To finish the proof we shall show that if $1 < l < k$, then G has a Hamiltonian cycle, which contradicts the assumptions about G .

Indeed, let H be the graph induced by the set $X \cup Y$. Since $K_l \vee \overline{K}_k \subset H$ and $l \geq 2$, we see that H is 2-connected. Further, if u and v are distinct nonadjacent vertices of H , with degrees d'_u and d'_v , they must belong to X , and so $d'_u = d_u = k$ and $d'_v = d_v = k$. That is to say,

$$d'_u + d'_v = 2k > k + l.$$

Theorem 11 implies that H is Hamiltonian-connected, and it is easy to see that G has a Hamiltonian cycle. The proof of Theorem 4 is completed. \square

3.4 Proof of Theorem 5

Proof Although this proof is very close to the proof of Theorem 4, we shall carry it in full, due to the numerous specific details.

Let $k \geq 1$, $n \geq k^3/2 + k^2/2 + k + 5$ and let G be a graph of order n , with $\delta(G) \geq k$. Write m for the number of edges of G , and set $\delta := \delta(G)$.

Assume that $\lambda(G) \geq n - k - 2$, but G has no Hamiltonian path. To prove the theorem we need to show that $G = N_k(n)$ or $G = K_{n-k-1} + K_{k+1}$. Note that, in view of Theorem 6, it is sufficient to prove that $\text{cl}_n(G) = N_k(n)$ or $\text{cl}_n(G) = K_{n-k-1} + K_{k+1}$, so this will be our main goal.

Clearly, $\text{cl}_n(G)$ has no Hamiltonian path and

$$\delta(\text{cl}_n(G)) \geq \delta(G) \geq k, \quad \lambda(\text{cl}_n(G)) \geq \lambda(G) \geq n - k - 2,$$

so for the rest of the proof we assume that $G = \text{cl}_n(G)$. The main consequence of this assumption is that

$$d_i + d_j \leq n - 2 \quad (15)$$

for every two nonadjacent vertices i and j .

Next, since G has no Hamiltonian path, Corollary 13 implies that there is an integer $s \leq n/2$ such that $d_s \leq s - 1$ and $d_{n-s+1} \leq n - s$. Obviously, $s \geq \delta + 1 \geq k + 1$, and we easily find an upper bound on $2m$:

$$\begin{aligned} 2m &= \sum_{i=1}^s d_i + \sum_{i=s+1}^{n-s+1} d_i + \sum_{i=n-s+2}^n d_i \\ &\leq s(s-1) + (n-2s+1)(n-s-1) + (s-1)(n-1) \\ &= n^2 - 2sn + 3s^2 - s - n. \end{aligned}$$

Clearly, the expression $n^2 - 2sn + 3s^2 - s - n$ is convex in s ; hence it is maximal in s for $s = \delta + 1$ or $s = n/2$. Hence, either

$$2m \leq n^2 - 2(\delta + 1)n + 3(\delta + 1)^2 - (\delta + 1) - n \quad (16)$$

or

$$2m \leq \frac{3}{4}n^2 - \frac{3}{2}n. \quad (17)$$

On the other hand, inequality (1) implies that

$$n - k - 2 \leq \lambda(G) \leq \frac{\delta - 1}{2} + \sqrt{2m - n\delta + \frac{(\delta + 1)^2}{4}}.$$

In view of Proposition 15, we get

$$n - k - 2 \leq \lambda(G) \leq \frac{k - 1}{2} + \sqrt{2m - nk + \frac{(k + 1)^2}{4}},$$

which, after some algebra, gives

$$2m \geq n^2 - 2kn + 2k^2 + 4k - 3n + 2. \quad (18)$$

We shall prove that $s = k + 1$. Indeed, if $s \geq k + 2$, then (16) and (17) imply that either

$$n^2 - 2(k+2)n + 3(k+2)^2 - (k+2) - n \geq n^2 - 2kn + 2k^2 + 4k - 3n + 2$$

or

$$\frac{3}{4}n^2 - \frac{3}{2}n \geq n^2 - 2kn + 2k^2 + 4k - 3n + 2.$$

Both of these inequalities lead to a contradiction, so we have $s = k + 1$ and thus $\delta = k$. Therefore,

$$d_1 = \dots = d_{k+1} = k.$$

Our next goal is to show that $d_{k+2} \geq n - 2k - 2 - k^2$. Indeed, suppose that

$$d_{k+2} < n - 2k - 2 - k^2.$$

Now we get

$$\begin{aligned} 2m &= \sum_{i=1}^{k+1} d_i + d_{k+2} + \sum_{i=k+3}^{n-k} d_i + \sum_{i=n-k+1}^n d_i \\ &< k(k+1) + n - 2k - 2 - k^2 + (n - 2k - 2)(n - k - 2) + k(n - 1) \\ &= n^2 - 2kn + 2k^2 + 4k - 3n + 2, \end{aligned}$$

contradicting (18). Hence $d_i \geq n - 2k - 2 - k^2$ for every $i \in \{k+2, \dots, n\}$.

Next, we show that the vertices $k+2, \dots, n$ induce a complete graph in G . Indeed, let $i \in \{k+2, \dots, n\}$ and $j \in \{k+2, \dots, n\}$ be two distinct vertices of G . If they are nonadjacent, then

$$\begin{aligned} d_i + d_j &\geq 2n - 4k - 4 - 2k^2 \\ &\geq n + k^3 + k^2 + 2k + 5 - 4k - 4 - 2k^2 \\ &= (n - 2) + k^3 - k^2 - 2k + 3 > n - 2, \end{aligned}$$

contradicting (15).

Write X for the vertex set $\{1, \dots, k+1\}$. Write Y for the set of vertices in $\{k+2, \dots, n\}$ that have neighbors in X . If $Y = \emptyset$, then G is a disconnected graph and the order of its largest component is at most $n - k - 1$. Also X induces a K_{k+1} . Clearly, the inequality $\lambda(G) \geq n - k - 2$ implies that $G = K_{n-k-1} + K_{k+1}$, completing the proof if $Y = \emptyset$.

Now, suppose that $Y \neq \emptyset$. We shall show that every vertex in Y is adjacent to every vertex in X . Indeed, suppose that this is not the case, and let $w \in \{k+1, \dots, n\}$, $u \in X$, $v \in X$ be such that w is adjacent to u , but not to v . We see that

$$d_w + d_v \geq n - k - 1 + k = n - 1,$$

contradicting (11).

Next, let $l := |Y|$ and note that $1 \leq l \leq k$, as $d_1 = k$. If $l = k$, then $G = N_k(n)$. To finish the proof we shall show that if $1 \leq l < k$, then G has a Hamiltonian path.

Indeed, let H be the graph induced by the set $X \cup Y$. Further, if u and v are distinct nonadjacent vertices of H , with degrees d'_u and d'_v , they must belong to X , and so $d'_u = d_u = k$ and $d'_v = d_v = k$. That is to say,

$$d'_u + d'_v = 2k \geq k + 1 + l.$$

Theorem 10 implies that H contains a Hamiltonian cycle, and hence G has a Hamiltonian path. The proof of Theorem 5 is completed. \square

3.5 Proofs of Propositions 8 and 9

Proof of Proposition 8 Suppose that $2k + 1 \leq n \leq k^3/2 + k + 1$, and consider the graph $M_k(n)$. Write X for the set of vertices of $M_k(n)$ of degree k , let Y be the set of their neighbors, and let Z be the set of the remaining $n - 2k$ vertices of $M_k(n)$. Select two distinct vertices $u \in Z \cup Y$ and $v \in Z \cup Y$, remove the edge $\{u, v\}$, and write G for the resulting graph.

To begin with, note that $\delta(G) \geq k$ and G is a proper subgraph of $M_k(n)$. To complete the proof we define a unit n -vector \mathbf{x} and show that

$$\lambda(G) > \langle A(G) \mathbf{x}, \mathbf{x} \rangle \geq n - k - 1.$$

Thus, let

$$x = \frac{2}{k^2 \sqrt{n - k + 4/k^3}}, \quad y = \frac{1}{\sqrt{n - k + 4/k^3}},$$

and define the n -vector $\mathbf{x} := (x_1, \dots, x_n)$ as

$$x_i := \begin{cases} x, & \text{if } i \in X; \\ y, & \text{if } i \in Y \cup Z. \end{cases}$$

Note that $\|\mathbf{x}\| = 1$, because

$$\|\mathbf{x}\|^2 = kx^2 + (n - k)y^2 = \frac{4}{k^3(n - k + 4/k^3)} + \frac{n - k}{n - k + 4/k^3} = 1.$$

Therefore,

$$\begin{aligned} \lambda(G) &\geq \langle A(G) \mathbf{x}, \mathbf{x} \rangle = (n - k)(n - k - 1)y^2 - 2y^2 + 2k^2xy \\ &= (n - k)(n - k - 1)y^2 + 2y^2 \\ &= \frac{n - k}{n - k + 4/k^3}(n - k - 1) + \frac{2}{n - k + 4/k^3} \\ &= n - k - 1 - \frac{4}{k^3(n - k + 4/k^3)} \left(n - k - 1 - \frac{k^3}{2} \right) \\ &\geq n - k - 1. \end{aligned}$$

Finally, the inequality $\lambda(G) \geq \langle A(G) \mathbf{x}, \mathbf{x} \rangle$ is strict, because obviously \mathbf{x} is not an eigenvector to $\lambda(G)$. \square

Proof of Proposition 9 Suppose that $2k+1 \leq n \leq k^3/2 + k^2/2 + k + 2$, and consider the graph $N_k(n)$. Write X for the set of vertices of $N_k(n)$ of degree k , let Y be the set of their neighbors, and let Z be the set of the remaining $n - 2k - 1$ vertices of $N_k(n)$. Select two distinct vertices $u \in Z \cup Y$ and $v \in Z \cup Y$, remove the edge $\{u, v\}$, and write G for the resulting graph.

To begin with, note that $\delta(G) \geq k$ and G is a proper subgraph of $N_k(n)$. To complete the proof we define a unit n -vector \mathbf{x} and show that

$$\lambda(G) > \langle A(G) \mathbf{x}, \mathbf{x} \rangle \geq n - k - 2.$$

Thus, let

$$x = \frac{2}{k(k+1) \sqrt{n-k-1+4/k^2(k+1)}}, \quad y = \frac{1}{\sqrt{n-k-1+4/k^2(k+1)}},$$

and define the n -vector $\mathbf{x} := (x_1, \dots, x_n)$ as

$$x_i := \begin{cases} x, & \text{if } i \in X; \\ y, & \text{if } i \in Y \cup Z. \end{cases}$$

Note that $\|\mathbf{x}\| = 1$, because

$$\begin{aligned} \|\mathbf{x}\|^2 &= (k+1)x^2 + (n-k-1)y^2 \\ &= \frac{4}{k^2(k+1)(n-k-1+4/k^2(k+1))} + \frac{n-k-1}{n-k-1+4/k^2(k+1)} = 1. \end{aligned}$$

Therefore,

$$\begin{aligned} \lambda(G) &\geq \langle A(G) \mathbf{x}, \mathbf{x} \rangle = (n-k-1)(n-k-2)y^2 - 2y^2 + 2k(k+1)xy \\ &= (n-k-1)(n-k-2)y^2 + 2y^2 \\ &= \frac{(n-k-1)(n-k-2)}{n-k-1+4/k^2(k+1)} + \frac{2}{n-k-1+4/k^2(k+1)} \\ &= n-k-2 - \frac{4}{k^2(k+1)(n-k-1+4/k^2(k+1))} \left(n-k-2 - \frac{k^2(k+1)}{2} \right) \\ &\geq n-k-2. \end{aligned}$$

Finally, the inequality $\lambda(G) \geq \langle A(G) \mathbf{x}, \mathbf{x} \rangle$ is strict, because obviously \mathbf{x} is not an eigenvector to $\lambda(G)$. \square

4 Concluding remarks

It should be noted that most of the results discussed in the present paper and in the references [1, 10, 13, 14, 15, 16, 17, 21] deal exclusively with very dense graphs, which makes these results somewhat one-sided. Hoping to change this tendency, we would like to state two open problems.

First, recall that Dirac's theorem [6] is probably the most famous sufficient condition for Hamiltonian cycles. Yet, no comparable spectral statement seems to be known so far.

Problem 16 *Find a spectral sufficient condition for Hamiltonian cycles that would imply Dirac's sufficient condition.*

Second, a deep result of Krivelevich and Sudakov [12] establishes a sufficient condition on the second largest singular value of a regular graph that implies existence of Hamiltonian cycles. Two attempts have been made to extend this result to nonregular graphs, but these extensions forsake the adjacency matrix for other matrices ([4], [8]), so comparisons are difficult.

Hence, it is worth to reiterate the following problem, first raised in [12]:

Problem 17 *Extend the result of Krivelevich and Sudakov to nonregular graphs, using the second largest singular value of the adjacency matrix.*
